

Quantum Key Distribution

Norbert Lütkenhaus

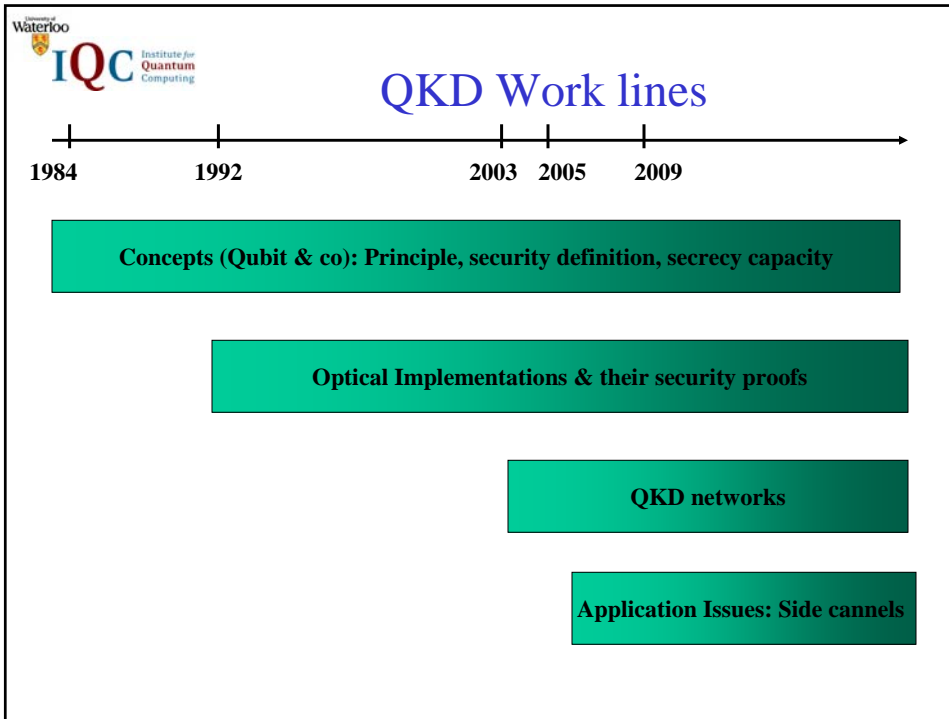

The Starting Point ...

**Quantum Mechanics allows
Quantum Key Distribution,
which can create an unlimited amount of secret key using**

- a quantum channel**
- an authenticated classical channel**

**without imposing limitations
on an adversary's resources!**

Note: no secret key can be generated by
-the use by an authenticated classical channel alone
nor if one additionally provides
-some finite amount of secret seed key
(the latter being one method to generate an authenticated classical channel)

Work line I: Concepts

what exactly do we mean by ‘secure key’?
 Universal composable security definition [Renner, PhD thesis 2005]

$$\|\rho_{ABE} - \rho_{AB} \otimes \rho_C\|_1 \leq \epsilon$$

Under which conditions can we generate secret key

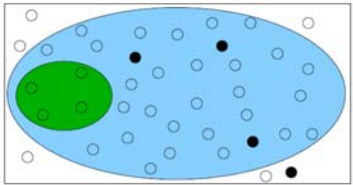

- 1) given many copies of ρ_{AB} ?
 Horodecki³, Oppenheim (2005): Private states (secret key from bound entangled states)
- 2) given measurement results from many copies of ρ_{AB} ?
 Unknown! (Necessary condition: correlations must show entanglement signature!)

Tools for security proofs:
 Quantum DeFinetti Theorem [Renner, PhD thesis 2005]
 Collective attack = coherent attack

Exploration of new security scenarios:
 bounded storage model [Damgard, Fehr, Salvail, Schaffner, 2005]
 Assume limited quantum storage of adversary

- ➔ allows also other cryptographic primitives such as bit commitment
- ➔ can be run on BB84 hardware

Quantum DeFinetti Theorem
[Størmer 1969; ... Caves, Fuchs, Schack 2002]
[Renner, PhD thesis 2005]
[Renner, Nature, 2007]

general state of N systems

↓ permutation

symmetric state of N systems

↓ subset of n systems

$$\rho^{(n)} \rightarrow \sum_i p(i) \prod (\otimes \rho_i + \text{Rest}) \prod$$

Quantum DeFinetti theorem is at the heart of QM experiments:
how and why can we assign density matrices to sources?

Application also in entanglement verification (e.g. entanglement witnesses)
[\[van Enk, NL, Kimble, Phys. Rev. A 75, 052318 \(2007\)\]](#)

Gap or no gap:
are all quantum correlations useful?

QKD (BB84 protocol)

one-way bound 14,6%

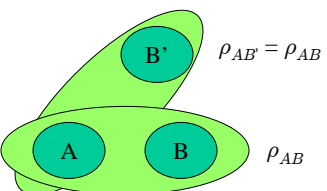

loss of quantum correlations 25%

20% **GAP?**

[Gottesman/Lo] [Chau]

symmetric error rate

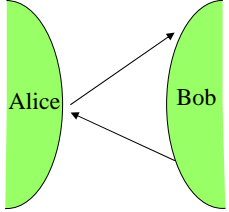

limit for one-way communication:
data should not be explainable
 ρ_{AB} which is symmetrically extendible

$\rho_{AB'} = \rho_{AB}$

ρ_{AB}

Existence of symmetric extension
→ marginal problem
existence of ρ_{ABE}

two-way communication

1) no known first-round communication breaks symmetric extension in gap area
[\[Myhr, Renes, Doherty, NL, PRA 79, 042329 \(2009\)\]](#)

2) Conjecture of simple criteria for two-qubit case
[\[Myhr, NL, arXiv:0812.3667\]](#)

Workline II: Optical Schemes

Experimental implementations:

- weak laser pulses
- Photon-pair sources

Security proofs:

- finding the qubit in optical modes space!
- no single-photon sources required for unconditional security

Improved optical schemes:

- decoy state QKD:
- Photon-pair schemes with untrusted source
- Strong-reference pulse schemes

- continuous variable QKD
- differential-phase-shift QKD

key rate G scales as
 $G \sim \eta$
 with transmittivity η
 → same as with ideal single photon source

Improved detectors:

- detector noise limits distance
 - detector saturation limits key rate
- } up-conversion detectors (Stanford)
 superconducting detectors (NIST)
 self-referencing detectors

→ GHZ clock rates, distances more than 100 km

Summary Reduction

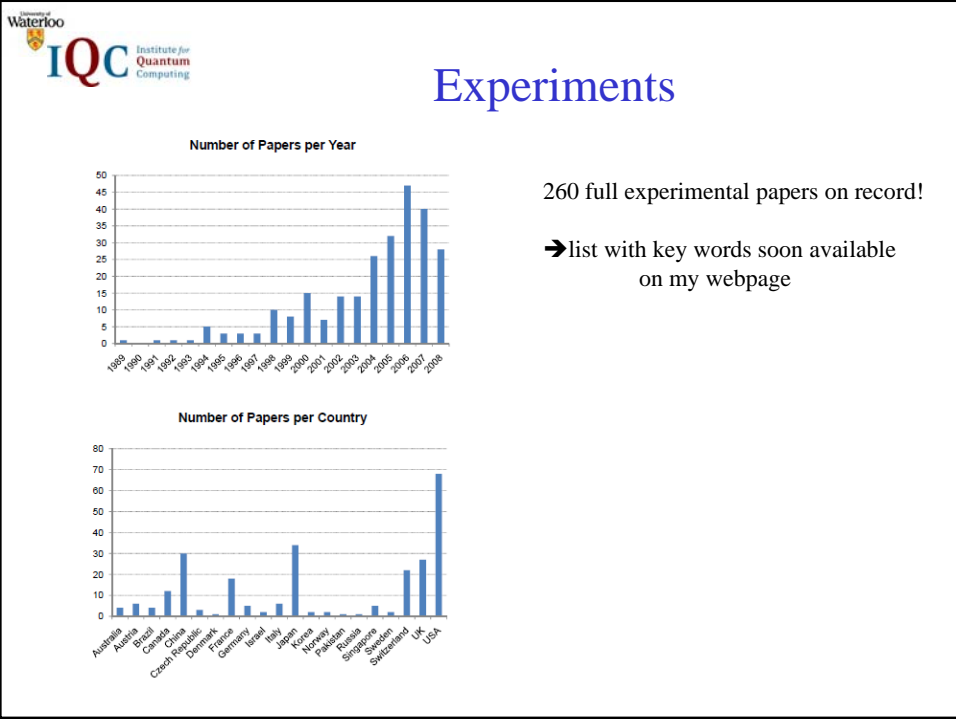

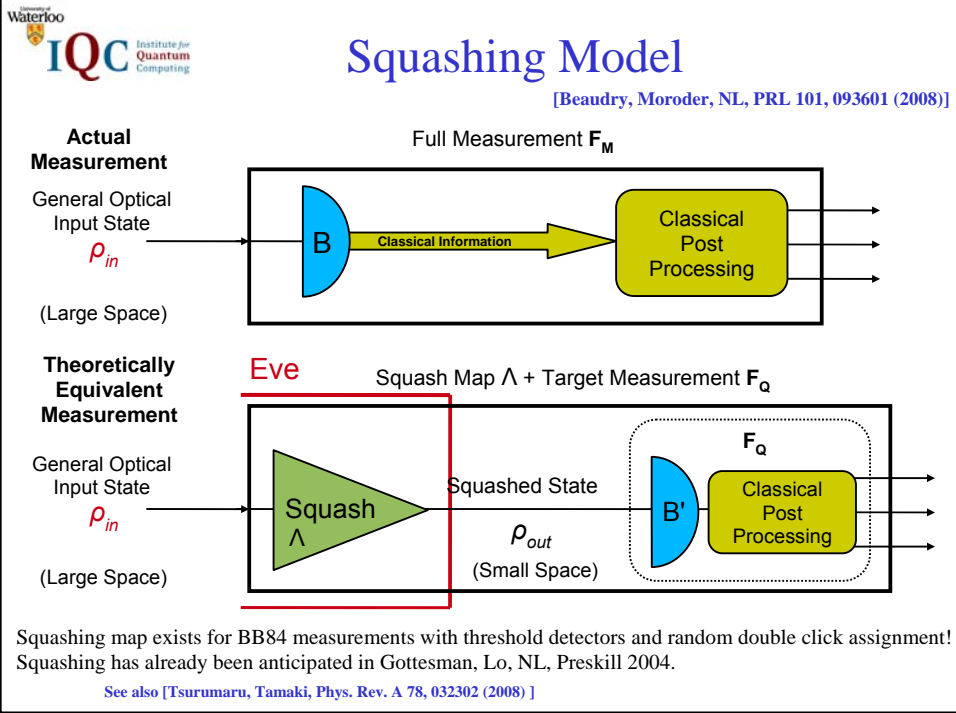

Model

Reality

channel testing: decoy method
 [Hwang; Lo; Wang]

Toshiba/NIST/Los Alamos/... One way weak pulse QKD (phase encoding)

Security well established:

- weak pulse
- decoy state
- squashing model for detector

These systems drive detector development!
 → GHz clockrate (NIST)

1) Keep an eye on amplitudes in phase encoding!

loss in the two arms might be different!

2) fast mode-lock lasers or amplitude modulated continuous signals don't work with the standard security proofs!

Differential Phase Shift QKD

[Inoue, Waks, Yamamoto PRA 68 022317 (2003)]

Elegant set-up adapted to optical networks ...

no full security proof so far!
long pulse train looks like ONE high-dimensional signal!

Need to develop new tricks to break the problem down ...

Work line III: Application Aspects

Side channel: Optical protocols are unconditional secure

BUT

That does not mean that the optical implementation is secure ...

(Same as in classical crypto: side channels, trojan horses ...)

Specific attacks:

extra degrees of freedom in signal (residual from signal preparation) (Weinfurter)

Detector Flashback (Kurtsiefer, Weinfurter)

Mismatch of detection windows:

faked state attack (Makarov)

time shift attack (Lo et al)

Countermeasures:

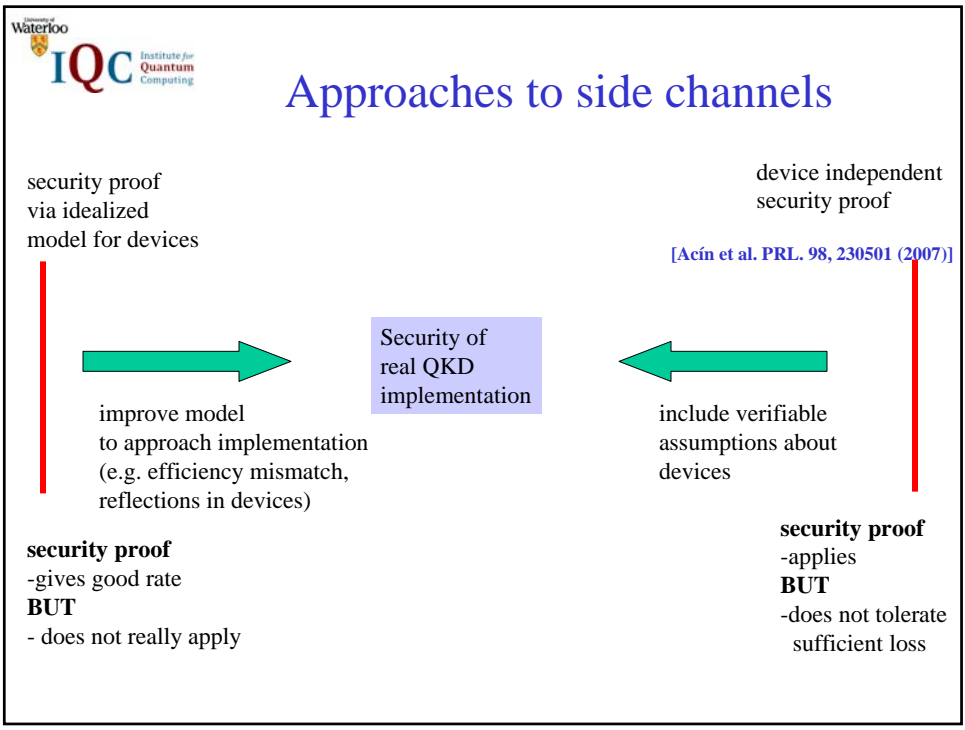

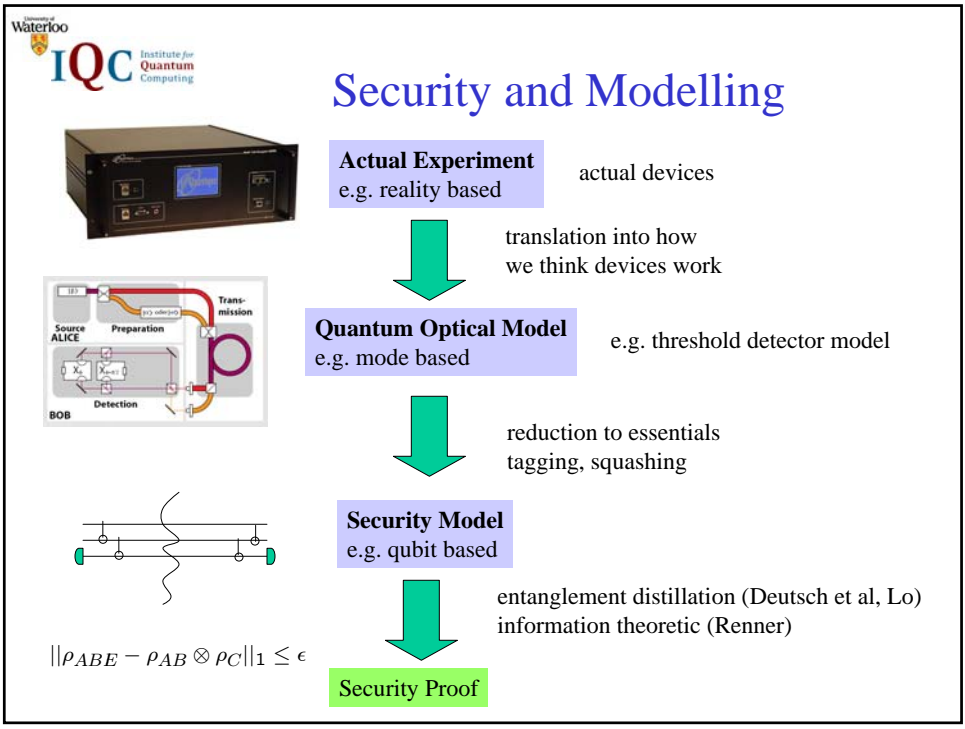

-Theory: estimate damage, include in privacy amplification (GLLP)

-Experiment: better engineering (optical isolators, precise timing)

-Theory: use fundamentals of Quantum Mechanics: Device Independent Security Proofs

Finite size effects: 100 received signals cannot be turned into secret key

so how many are needed? Guess is 10^6 , but it might be 10^{10} ... depends on proof technique!

Work line IV: networks

- 1) Trusted repeater networks
 (made up from point-to-point connections)
- 2) Full quantum networks (→ Talk Jeff Kimble)

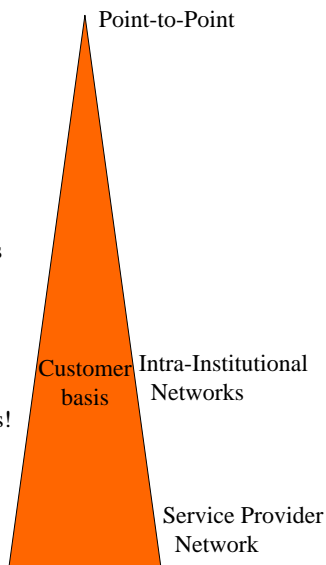

Trusted repeater network:
 larger customer base

Interdisciplinary effect:
 combination of quantum effects (point-to-point)
 and classical crypto protocols (secret sharing)
 → network stability, stability against some corrupted nodes

Topology of trusted repeater network:
 optimum cell size about 20 km (cost optimization)
 → new optimization direction for point-to-point links!
 (not only maximum distance)

Make precise the leverage QKD has in addressing real needs!
 Solve key management problems, initialization etc...

Note:
 authentication key (Carter/Wegman) needs to be secure
 only for short time!

Network types

Trusted repeater networks: (technologically easy) [Application: User=Operator]
 Connect trusted repeater stations by point-to-point QKD devices

Realisations:
 DARPA Network 2002-2005
 SECOQC Network 2004-2008

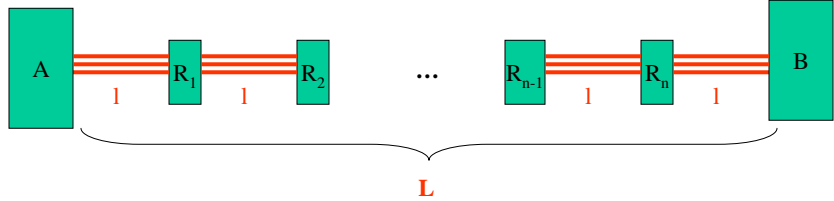

Combine Classical with Quantum Cryptography:
 independent paths allow secure key as long as at least one path is not compromised

Quantum repeater network: (technologically challenging) [Application: Service Provider]
 Overcomes loss problem
 allows routing

Example: Linear Chain
 [Alleaume, Roeff, Diamanti, NL, quant-ph/0903.0839]

User demand: rate G
QKD characteristics: secret key rate $g(d)$
Cost: $C_{network} = C_{link} \frac{L}{l} \frac{K_{target}}{k(l)}$

sequential links # parallel links

$k(l) \sim \eta = 10^{-\alpha} l/10$
 $\rightarrow l_{opt} = \frac{10}{\alpha \ln(10)}$
 $\rightarrow \alpha = 0.25 \text{ dB/km} \rightarrow l_{opt} = 17.5 \text{ km}$

Summary

QKD is neither purely engineering, nor is it just a theory toy ...

- by definition, security is a theoretical statement
- by definition, only implementation realizes QKD

Ongoing interaction between:

- cryptographers
 - who provide the goal, security definition, tools
- quantum theorists
 - for security proofs and system analysis
- system experimentalists
 - who devise practical schemes
- device experimentalists
 - who build and optimize devices such as detectors

QKD drives and is driven by broader Quantum Information Theory

- Quantum Definetti Theorem, Symmetric Extendibility of Quantum States, Channel Capacities ...
